The wildland urban interface (WUI) geospatial data standard defines minimum attribution for interagency collaboration and data sharing.

Status: Approved

Source Record: N/A

System of Record: N/A

Data Stewardship Group: Geospatial Subcommittee

Data Steward: Joe Kafka

Additional Text: The standard will define the geospatial data "container" for WUI areas, but not address how WUI is defined. The wildland urban interface (WUI) geospatial data standard defines minimum attribution for interagency collaboration and data sharing. Data transfer/exchange.

**Background:** In May of 2008, the NWCG Wildland Urban Interface Working Team performed a review and evaluation of the National Fire Protection Association (NFPA) 114 3.3.28, NWCG, and Healthy Forest Restoration Act (HFRA) definitions of the Wildland Urban Interface (WUI). And Federal Register 66: 751, Urban Wildland Interface Community Definition, [https://www.federalregister.gov/articles/2001/01/04/01-52/urban-wildland-interface-communities-within-the-vicinity-of-federal-lands-that-are-at-high-risk-from#p-15](https://www.federalregister.gov/articles/2001/01/04/01-52/urban-wildland-interface-communities-within-the-vicinity-of-federal-lands-that-are-at-high-risk-from#p-15). The working team identified that, “designation of communities at risk should be the responsibility of the local authority having jurisdiction who are aware of the local factors affecting the wildland urban interface, changing topographical factors, weather, community use, etc.” It was the consensus of the team working on this GIS data layer standard that it may not be possible or necessary to capture all of the characteristics that may be used to define the WUI in locales across the country. However, it is important to provide a basic shared structure for storing WUI features, understanding that the WUI features may overlap and may be determined using different and sometimes conflicting methods.

**Abstract:** The WUI geospatial data layer standard defines a single layer that may represent the extent of the WUI and document the method used by the responsible unit to delineate the WUI. **The standard will define how WUI is attributed, but not address how WUI is defined.** The wildland urban interface (WUI) geospatial data standard defines minimum attribution for interagency collaboration and data sharing.

**Purpose:** A basic structure with minimum attribution for interagency collaboration and data sharing of WUI features, understanding that the WUI features may overlap and may be determined using different and sometimes conflicting methods.

**Data Model:** WUI areas would be depicted as polygon shapefile or polygon feature class in a geodatabase.

**Other Notes:** The standard will define how WUI is attributed, but not address how WUI is defined.

**Related Layers:** Fuels Treatment Polygons, Ownership Boundaries & Facilities/Structures (agency), Communities, Urban Areas, Infrastructure, Fire Protection Responsibility.
### Horizontal and/or Vertical Position Accuracy:

Standards for horizontal and vertical accuracies are detailed in Geospatial Positioning Accuracy Standards; Part 3: National Standard for Spatial Data Accuracy (NSSDA), [http://www.fgdc.gov/standards/projects/FGDC-standards-projects/accuracy/part3/chapter3](http://www.fgdc.gov/standards/projects/FGDC-standards-projects/accuracy/part3/chapter3). Accuracy is reported by feature in meters at the 95% confidence level listed in the HAccuracy and/or VAccuracy fields. Accuracy reported at the 95% confidence level means that 95% of the positions in the feature will have an error with respect to true ground position that is equal to or smaller than the reported accuracy value.

### Horizontal and/or Vertical Spatial Reference Information:

Data layer projection parameters should be documented in a .prj file (shapefile format) or in a geodatabase projection definition. Or, specify the projection parameters via an EPSG code (example EPSG code 4326 = WGS84), [http://www.epsg-registry.org](http://www.epsg-registry.org). Projection parameters file should include applicable attributes as specified in the FGDC Standards Reference Model, 4.1.2.1.23.

</table>

*Standard field names should be used for the core attributes when possible. Alternate field name suggestions are given to accommodate database conflicts and legacy datasets. Alternate name use should be documented in the Other Notes section above.

** GUIDs are unique specially formatted numeric strings generated by a “GUID generation tool.” GUIDs can be generated at http://www.guidgenerator.com/.

The purpose of the GeometryID is to ensure that every unique object has a unique ID. This is important in an enterprise implementation where data is coming from many sources to determine if an object is unique or if it has been duplicated. Between the GlobalID and the FireOccurID (IRWINID) the unique geometry may be determined.

Users should generate a GeometryID for each unique record they create (spatial or non-spatial) for NWCG datasets. It is the data creators responsibility to create and maintain this ID for the life of that particular record. It is the responsibility of the person doing the data aggregation at a regional or national level to maintain this GUID as well. A GUID can be created in multiple ways - on a cell by cell basis using a website or script to generate a unique GUID, on a group of records using a script, or it can be automatically generated by the users GIS software or tools.
