The *Guide to Preventing Aquatic Invasive Species (AIS) Transport by Wildland Fire Operations* is a product of, and maintained by, the Invasive Species Subcommittee (ISSC), a component of the Equipment Technology Committee of the National Wildfire Coordinating Group (NWCG). The ISSC provides national leadership in the prevention of invasive species transport by wildland fire mobile equipment and related vehicles, and its primary objectives are to:

- Develop and disseminate practical standards, guidelines, best practices, and recommendations to prevent the spread of invasive species.
- Integrate new and evolving information from the natural resource management community into the invasive species control effort.
- Evaluate and recommend wildland fire and support vehicle utilization and/or decontamination techniques, equipment, or products to minimize invasive species transport.

Questions and comments may be emailed to: BLM_FA_NWCG_Products@blm.gov.

This publication is available electronically from the NWCG Web site at: https://www.nwcg.gov/publications/444.

Chapter 1  Purpose

The *Guide to Preventing Aquatic Invasive Species Transport by Wildland Fire Operations* is intended to help wildland firefighters avoid the spread of aquatic invasive species. The *Guide* includes:

- Best management practices (BMPs) to prevent contact with and spread of invasive species,
- The best procedures for decontaminating ground and aviation equipment,
- AIS prevention recommendations for resource advisors, and
- AIS of concern to firefighters nationwide and disinfection methods.

Chapter 2  Aquatic Invasive Species and Why We Care

WHAT ARE THEY?
Aquatic invasive species are harmful, non-native plants, animals, and microorganisms living in aquatic habitats that damage ecosystems or threaten commercial, agricultural, and recreational activities.

WHY DO WE CARE?
Firefighter and public safety is our first priority, but aquatic invasive plants and animals pose a risk to native species, hydropower facilities and water supplies, and to firefighting equipment. Avoidance and decontamination can prevent the spread of these organisms and help assure that firefighting equipment remains operational. See *Appendix D: Aquatic Invasive Species of Concern to Firefighters* for information on the species firefighting resources are most likely to encounter, including their distributions, disinfection methods, and references.

WHERE DO AIS COME FROM?
Aquatic invasive species can be found in the untreated water sources used in firefighting operations, either a natural source (a river or lake) or a human-made water body (a reservoir, canal, or stock tank) that has not been treated for municipal use or human consumption. Municipal water distributed via hydrants is not considered a reservoir of invasive species. Untreated water sources may harbor a variety of AIS, including quagga and zebra mussels, New Zealand mudsnails, whirling disease, didymo (*or rock snot*), and plants such as hydrilla, Eurasian watermilfoil, and giant salvinia, as well as many vertebrate species. In some cases, the occurrence of aquatic invasive species in a water body is well documented, but for many western waters such information is incomplete or nonexistent.

HOW DO AIS GET MOVED AROUND?
In wildland fire management, AIS can be transported via firefighting equipment that contacts or transports untreated water, such as portable pumps (including floatable pumps), portable tanks, helicopter buckets, and internal tanks of fire engines, water tenders, helicopters, and fixed wing aircraft. Typically, components of the equipment that cannot be drained and dried completely are most likely to harbor invasive species and thus serve as vectors. Residual water left in incompletely drained tanks in equipment moved between fire incidents is of special concern: quagga mussel larvae are able to survive 5 days in summer and 28 days in autumn in residual water contained within undrained boats (*Appendix D*, Choi et al. 2013), a time interval which is well within the re-deployment period for most firefighting equipment.
There are many possible invasion pathways for AIS within the context of wildland fire incident response. During an incident, untreated water is routinely moved between watersheds and sometimes between basins. Typically, large water bodies, such as reservoirs, serve as primary sources to fill various types of firefighting equipment, which then transport and disperse that water to other parts of the fire. In many fire incidents, helicopters equipped with snorkels and internal tanks or buckets draft or dip from untreated water sources, then may draft from a new source with contaminated gear.

**HOW IS FIRE EQUIPMENT AFFECTED BY AIS?**

Invasives such as zebra mussels and New Zealand mudsnails may adhere to the surfaces of tanks, pumps, and hoses. They can be transmitted to uncontaminated water sources if this equipment is not drained and dried completely or decontaminated.

**Chapter 3   Guidelines and Best Management Practices**

**GENERAL PREVENTION**

Preventing exposure to AIS through best management practices is the easiest and simplest way to control their spread.

- Map the distribution of aquatic invasive organisms in watersheds where the operation will take place (Figure 1). See Chapter 6 for sources for maps or GIS layers showing locations of AIS infested waters. You can never be certain that invasives are NOT present, but at least you will know ahead of time where they ARE known to be present.

- Fill tanks from municipal water sources whenever possible.

- When possible, avoid drafting from waterbodies with known infestations of aquatic invasive species.

- Avoid transferring water between drainages or between unconnected waters within the same drainage. Do not dump water from one waterbody (e.g., stream, lake, or reservoir) into another waterbody. Do not allow water from fold-a-tanks or pumpkins to drain into nearby waterways if the fold-a-tank was filled with water from a different drainage. Dispose of excess water over uplands.

- Avoid sucking organic and bottom material into water intakes when drafting from shallow water. Use screens. If collapsible tanks can be filled with municipal water, draft from those tanks instead of untreated water sources.

- Avoid entering (driving through) water bodies or wet areas when possible.

- Remove all plant parts and mud from external surfaces of gear and equipment after an operational period.

- Avoid obtaining water from multiple sources during a single operational period unless drafting/dipping equipment is decontaminated or changed out with clean equipment between sources.
If contamination of equipment with untreated water or mud/plants is unavoidable, see “Decontaminating Ground Equipment” and “Decontaminating Aviation Equipment”, below.

Chapter 4 Ground Operations

Of great concern for ground equipment is the possibility that residual tank water contaminated with AIS could be transferred to uncontaminated waterbodies during the drafting process. However, if proper drafting and water handling BMPs are used and foot valves are working correctly, there is low risk that contaminated tank water could "seep" into the drafting water source.

WATER HANDLING OPERATIONS

- When possible, fill engines from a municipal hydrant, a water tender, or from a pump assigned to a single drafting source.

- When spraying water to suppress a fire, avoid application of untreated water into local water bodies (ponds, lakes, rivers, streams, wetlands, seeps, or springs), especially if the water in the tank came from a different watershed (Figure 2). Water delivery equipment and accessories (e.g., fireline hoses, wye valves, nozzles) that do not transfer tank water to waterbodies do not need to be decontaminated.

- To prevent leakage and to maintain the prime, be sure that foot valves are screwed snugly onto drafting hoses and are fully closing and not leaking before and during drafting (Figure 3). If foot valves are leaking, refrain from drafting and replace foot valve with one that is operating properly. See Appendix B for methods to field test foot valves for leakage.

Figure 2. Water delivery equipment is low risk if contaminated water is pumped onto a fire and not applied to another waterbody.

Figure 3. Be sure foot valves are not leaking before and during drafting.
• **Priming the engine pump for drafting** —
To minimize the potential for engine water leakage through the foot valve, **prime with water from the drafting source rather than using water from the engine tank** (Figure 4). When priming by filling the drafting hose with a bucket, first make sure that the bucket is clean so that it does not transfer AIS. Additionally, don’t leave draft hose full with foot valve engaged and submerged in water source when not pumping.

• Elevate foot valves above the bottom of the waterbody for clean, sediment-free operation—for example, duct tape foot valve to a shovel or place the valve in a hard hat or bucket.

• Remove water drain plug/s from self-priming pumps (e.g., trash pumps) to empty pump housing before moving to a new waterbody.

• When filling the engine tank, avoid tank overflow into the water source.

### DECONTAMINATING GROUND EQUIPMENT

• Before moving to a new water source (in a different watershed), decontaminate all external and internal surfaces of foot valve and draft hose. Three options are:
  - Power wash with hot water (140° F, allow spray to contact surfaces for 2 minutes) using a hot pressure washer (e.g., a ‘Hotsy’).
  - Dry the gear in the hot sun until completely dry to the touch (sunlight intensifies the decontamination process).
  - Use a chemical solution (see *Appendix A: Decontaminating with Chemical Disinfectants*). Surfaces of the drafting hose and foot valve can be decontaminated by coiling and submerging in a bucket filled with disinfectant (Figure 5) or by spray application with a backpack pump or a large spray bottle.

• Consider carrying spare, clean, dry draft hoses and foot valves to switch out with used ones when moving to a new water source.
Chapter 5  Aviation Operations

Aircraft such as air tankers and single engine air tankers, which use water from municipal sources, are unlikely to encounter AIS and are not addressed here. All other aircraft utilize untreated water and have the potential to transfer AIS.

GENERAL PREVENTION

- Avoid dipping or scooping water from multiple water sources within the same operational period to minimize cross-contamination of water sources.
- If possible, use water dipped from the same drainage that it will be dropped in. This can be accomplished by setting up heliwells (portable tanks/pumpkins) filled from small streams with Mark III pumps.
- Use deeper (blue) water whenever possible. Avoid areas that will intake mud or plants.
- Switch out a contaminated helicopter bucket with a clean bucket before moving to a new water source. Alternating used (possibly contaminated) helicopter buckets with spare (clean) buckets can save time and increase efficiency, as the first bucket can be decontaminated while the second bucket is being used.
- Helicopter snorkels do not need to be primed with either source or tank water, so there is no risk of residual tank water entering a water source during drafting operations (Figure 6). However, snorkel ends and foot valves that encounter untreated water must still be decontaminated.

DECONTAMINATING AVIATION EQUIPMENT

Chemicals such as bleach and quaternary ammonium compounds do not meet corrosion requirements for aluminum and shall not be used on aircraft fuselages or water delivery components such as helicopter buckets and footvalves.

- Visually inspect water handling equipment (snorkel hoses, pumps, foot valves, screens, buckets, intakes and tanks) for mud, debris, or plant parts daily, during maintenance, and after every water dropping mission, when possible. Remove plants and mud from external surfaces.
- When contact with untreated water has occurred or is suspected, decontamination is needed. Thorough drying in the hot sun alone is an easy and effective decontaminating method, though required drying times can vary with equipment materials (e.g., metal, rubber, fabric). Dry gear in the sun until it’s completely dry to the touch. Drying may not be possible for a quick turnaround, so carry spare, clean gear to switch out with wet gear.
- Alternatively, clean and decontaminate accessible, exposed surfaces by power washing with hot water (140°F) for 2 minutes before moving to new, unconnected water sources or new incidents. If a helicopter bucket has a butyl (rubber) valve seal, avoid prolonged application of hot water spray to the seal to prevent softening of this vulnerable material. Power washing greatly reduces the likelihood that any target aquatic invasives are present.
• When hot water (140°F) is not available or practical, use potable water to flush invasive species from the system. Ensure that run-off cannot reach a water source.

DECONTAMINATING ACCESSIBLE INTERNAL TANKS

Accessible tanks have doors or other openings that allow access for cleaning. Scooper aircraft (CL215 or CL415, and Fire Boss), Sky Crane helicopters (CH-54/S-64), and other tanked helicopters are examples of aircraft with accessible tanks.

• Decontaminate internal tanks by spraying the internal surface with hot water (140°F) from a hot pressure washer (e.g., a ‘Hotsy’). Allow spray to contact surface for at least 2 minutes. This method is recommended for scooper and Fire Boss aircraft (Figure 7). Tanked helicopters have tank doors that open widely from below for easy tank access and draining. Hot water spray or thoroughly dry these surfaces.

Chapter 6  AIS Prevention for Resource Advisors

During fire events, Resource Advisors (READs) and Resource Advisors, Fireline (REAFs) play an integral part in guidance, facilitation of decontamination actions, acquisition of equipment, and education. Whether the READs have local knowledge or have been assigned to a fire from outside the area, they are a critical factor in reducing the risk of AIS spread.

LOCATING AQUATIC INVASIVE SPECIES

Maps of known AIS infestations are a valuable tool for READs to communicate which waterbodies to avoid for drafting (Figure 1, pg. 6). Currently there is no nationwide, central repository of maps or geospatial data identifying AIS infested waters, but regional or local information may be available. Ideally, mapping occurrence of AIS would be done as a preseason activity involving local aquatic specialists and fire staff. At that time, maps could be prepared and distributed to local fire staff who could then provide a handoff packet (if needed) during large fire events or for incoming personnel unfamiliar with the area. Bear in mind that many waterways have not been surveyed and the presence of aquatic invasive species may be unknown, which is why any source of untreated water could harbor AIS.

Maps or GIS layers showing locations of AIS infested waters for resource advising on a fire might be obtained from the following sources:

• Local agency administrators or aquatic specialists may have information. Sometimes local land management offices maintain AIS data and prepare maps as part of preseason planning.

• A number of agencies or States may also have AIS location data. These include:
  o United States Geological Survey (USGS) Nonindigenous Aquatic Species database (nationwide, does not include pathogens): https://nas.er.usgs.gov/
**Identifying High Priority Aquatic Resources at Risk**

In addition to locating known AIS infestations, READS should also take into consideration which waters have high resource values for protection from an unintended AIS transfer. These values include waterbodies with native fish populations, recreational fisheries, municipal and hydropower water sources, or pristine high elevation lakes. As with AIS positive waters, high priority aquatic resources should be mapped prior to the fire season, and included in AIS prevention communications to fire managers.

**Understand AIS and How Fire Activities Can Spread Them**

Educating yourself and others regarding AIS and their dangers is likely one of the best management tools available. AIS encompass many species, from mollusks to plants to pathogens, and can be transported and decontaminated in a variety of ways. (See Appendix D: Aquatic Invasive Species of Concern to Firefighters and Disinfection Methods for descriptions and disinfection methods for AIS that may be of concern during water handling fire operations.) In addition, AIS educational materials are available on State and federal agency invasive species websites.

AIS are most likely to be transported via firefighting equipment that contacts or conveys untreated water, such as portable pumps (including floatable pumps), portable tanks, helicopter buckets, and internal tanks of fire engines, water tenders, helicopters, and fixed wing aircraft. Residual water left in incompletely drained tanks in equipment moved between fire incidents can harbor AIS, and quagga mussel larvae are able to survive for days in residual water contained within undrained boats. However, BMPs targeting drafting procedures greatly reduce AIS risk from residual tank water.
KNOW THE BMPS AND DECONTAMINATION PROTOCOLS

Study the General Prevention best management practices, which are simple operational techniques to prevent contact with AIS at the outset. For example, prudent prevention practices would be avoiding transferring water between drainages, or not sucking organic and bottom material into water intakes when drafting. Also, educate yourself on methods of decontamination, and emphasize flushing with pressurized hot water, drying of equipment, and use of spare gear over using chemical disinfectants. Note that for hot water decontamination, the recommended temperature is 140°F with a contact time of 2 minutes. According to research studies, this combination of temperature and contact duration will kill the majority of AIS of concern to fire operations (See Appendix D). For the hardier species, such as whirling disease, the flushing action of pressurized hot water greatly decreases the likelihood of retention on equipment.

Refer people who do not know how to decontaminate their equipment to someone who can either do the work or train them how. Be knowledgeable of contract language associated with equipment cleaning and decontamination requirements (e.g., scooper aircraft and helicopters). Read the “Operational Guidelines for Aquatic Invasive Species” section of the Interagency Standards for Fire and Fire Aviation Operations (the Red Book) at: https://www.nifc.gov/policies/pol_ref_redbook.html. Talk to helicopter managers and air operations to see if they need additional information or equipment.

INTERNAL ENGINE TANKS AND DRAFTING METHODS

Of great concern in the past was the possibility that residual engine or helicopter tank water contaminated with AIS could be transferred to uncontaminated waterbodies during the drafting process. However, if proper drafting and water handling BMPs are used and foot valves are working correctly (see Appendix B), there is low risk that contaminated tank water could "seep" into the drafting water source.

By focusing on drafting techniques rather than the difficult decontamination of internal tanks, which may or may not contain AIS, we can abolish the use of large volumes of chemical disinfectants and instead rely on procedure. Priming the engine pump with source water and not using tank water to initiate the prime eliminates the possibility of residual tank water entering a new waterbody through a leaky foot valve. Offer to provide information or assist engine operators on how to perform a foot valve test for leakage. Ask them if they are able to prime their pumps with source, or stream, water rather than from the engine tank. (See Appendix B for methods to field test foot valves for leakage.)

Helicopter snorkels do not need to be primed with either source or tank water, so there is no risk of residual tank water entering a water source during helicopter drafting operations.

Minimal risk occurs when contaminated tank water is applied to fire and upland areas so long as it does not enter other waterbodies. Water delivery equipment and accessories (e.g., fireline hoses, wye valves, nozzles) that do not transfer tank water to waterbodies do not need to be disinfected.

Familiarize yourself with situations where risk of AIS transfer is highest, such as gear that contacts untreated water and later is moved to new watersheds or waterbodies. Or a helicopter bucket that has snagged water plants and mud. Be able to discuss these scenarios so that others understand that the objective is to reduce the possibility of moving AIS from one source to another.

Serve as a problem solver, not an enforcer of rules and practices! Use your expertise as a READ to explain the BMPs and why they are important for ecosystem health.
PREPAREDNESS: DECONTAMINATION PERSONNEL, EQUIPMENT, AND SUPPLIES

There is typically a lag time between the onset of a fire incident and the arrival of decontamination equipment, such as heated pressure washers. Once equipment arrives, there may not be personnel available that are trained in its safe operation. The following measures are recommended to ensure your unit is properly prepared to prevent the spread of AIS during fire operations:

- Secure heated pressure washing equipment for use on your unit or the larger area in which you work. If you are unable to purchase equipment, have contact information at the ready for local contractors, rental shops, and chemical supply houses.

- For ground operations, ensure access to disinfectants for instances where heated pressure washing equipment is not available or there is insufficient time to thoroughly dry equipment. Know which disinfectants to provide to engine operators (see Appendix A).

- Train personnel in the safe implementation of decontamination protocols and operation of equipment. Develop Risk Assessments or Job Hazard Analyses for each specific decontamination task or piece of equipment. See Appendix C for Risk Assessment templates for disinfecting fire equipment: “Operating Hot Water Pressure Washers”; “Disinfecting Field Gear With Quaternary Ammonium Compounds”; and “Disinfecting Field Gear With Chlorine Bleach”. Modify these to fit your particular situation and field unit.

- Secure all necessary Personal Protective Equipment (PPE) for pressure washing and use of chemicals, if appropriate.
Appendix A: Decontaminating with Chemical Disinfectants

Chemical disinfectants, though effective, can be hazardous, corrosive, and difficult to dispose of. However, when other decontamination methods, such as hot water or drying, are not options, chemicals can be used for small gear items ONLY (e.g., footvalves, draft hoses, or screens) in volumes appropriate for small buckets. Bleach and quaternary ammonium compounds do not meet corrosion requirements for aluminum and shall not be used on aircraft fuselages or aerial water delivery components such as helicopter buckets and snorkels.

Quaternary ammonium compounds (quats), common cleaning agents used in homes and hospitals, are safe for MOST gear and equipment when used at recommended concentrations and rinsed. Chlorine products are not emphasized for use in these guidelines because of their corrosiveness to fabrics, plastics, rubber, and metal and their limited effectiveness against snails. However, bleaches are extremely effective against certain invasive organisms (e.g., chytrid fungus, Port Orford cedar root disease) and are relatively inexpensive. (See Appendix D: Aquatic Invasive Species of Concern to Firefighters and Disinfection Methods.)

TO DECONTAMINATE GEAR WITH QUAT DISINFECTANTS:

The quaternary ammonium formulations Super HDQ® and Green Solutions High Dilution256® (which replaces the discontinued Sparquat 256®) were recently (see Appendix D, Stout et al. 2016) found to be most effective against a variety of AIS. Green Solutions Neutral Disinfectant® is a less concentrated version of Green Solutions 256®. These formulations can be used at concentrations according to their labels (see below). Soak gear in a bucket for 10 minutes. Alternatively, gear may be disinfected by spraying with quat from a backpack weed sprayer or spray bottle. Afterwards, rinse gear thoroughly in clean water. Quat compounds are highly toxic to aquatic organisms but are immobile in soil. Keep effluent, containing this product, at least 100 feet from lakes, ponds, streams or other waters. Do NOT allow product to enter storm drains, lakes, streams, or other waterbodies.

CHEMICAL DISPOSAL

Small quantities of diluted quaternary ammonium products or bleach which have been used to disinfect foot valves or other firefighting equipment may be disposed of in a sanitary sewer as allowed by the product label. Alternatively, used solutions of quaternary ammonium products or bleach may be disposed of by any application specified on product label direction, such as:

- Cleaning vehicle exteriors and tires by spray application of diluted materials
- For the prevention of mildew on non-porous surfaces
- Disinfection of toilets (including portable)

Always consult the product label in determining the appropriate PPE necessary for the mixing and use of these chemicals, and for final direction on a given products use and disposal. Do NOT allow these products to enter storm drains, lakes, streams, or other waterbodies.

SUPPLY SOURCES

These recommended chemicals are available through the U.S. Government Services Administration (GSA) https://www.gsaadvantage.gov or through local janitorial chemical suppliers.

1) **Green Solutions Neutral Disinfectant®**
   GSA (NSN# 3502-04) = $32 per case (4 gal) = $8 per gal = $.06 per oz = $.12 per gallon of mixed solution
   (Spartan Chemical Company; EPA registration #1839-169-5741)

2) **Green Solutions High Dilution 256®** (replaced Sparquat 256®)
   This formulation is **4X more concentrated** than Green Solutions Neutral Disinfectant® (see above)
Not carried by GSA, but can be purchased from local janitorial supply businesses. Distributor locations can be found at:  http://www.spartanchealth.com/where-to-buy

Cost = ~$140 per case (4 gal) = $35 per gal = $0.27 per oz = $0.13 per 1 gallon of mixed solution
(Spartan Chemical Company; EPA registration #1839-169-5741)

3) **Super HDQ®** (twice as concentrated as *Sanicare Quat 128®*)

GSA (NSN# 1204-04) = $71 per case (4 gal) = $18 per gal = $0.14 per oz = $0.07 per 1 gallon of mixed solution

(Spartan Chemical Company; EPA registration # 10324-141-5741)

4) **Liquid household bleach** (6% sodium hypochlorite) (e.g., Regular Clorox® Bleach)
Grocery stores, prices vary
Appendix B: Field Testing Foot Valves for Leaks

BACKGROUND INFORMATION

AIS can be found in the untreated water sources used in firefighting operations, either a natural source (a river or lake) or a human-made water body (a reservoir, canal, or stock tank). Untreated water sources may harbor a variety of AIS, including quagga and zebra mussels, New Zealand mudsnails, whirling disease, didymo (*rock snot*), and many others.

Of great concern for ground equipment is the possibility that residual tank water contaminated with AIS could be transferred to uncontaminated waterbodies during the drafting process.

Therefore, the following best management practices are recommended.

- Use a properly functioning and tested foot valve during drafting. Ensure the foot valve is screwed on snugly and not leaking.

- To minimize the potential for engine and water tender tank water leakage through the foot valve, *prime with water from the drafting source rather than water from the engine tank*. When priming using a bucket, first make sure that the bucket is clean prior to priming so the bucket does not transfer AIS. Additionally, during drafting and water tending operations don’t leave draft hose full with foot valve engaged and submerged in water source when not pumping.

- Care should be taken when drafting to minimize any potential of tank water to come in contact with drafting source; e.g., pump priming or overflow of engine tank when filling.

- Untreated tank water obtained in one location should never be directly discharged into a waterbody at a different location.

In order to be prepared, foot valves on engines and water tenders should be tested monthly during the fire season and whenever an apparatus is moved between waterbodies. The following protocol outlines a simple test method that can be implemented in the field. Because foot valves can leak at either low or high pressures, testing at both pressure levels is required to evaluate the potential for leakage during operational drafting conditions.

EQUIPMENT LIST

Some items may be part of an engine’s supplied equipment. Other items may need to be purchased but are easily found at fire equipment vendors.

**Items needed to perform the leak test include:**

- Suction hose and ratchet straps
- Assorted male-to-female adapters, increasers, and reducers

**If a pressure gauge is not present on equipment:**

- 1 ½” Pump Test Kit with Gauge – CFE (Cascade Fire Equipment) P/N: 11495 or similar
- 1 ½” 90 Degree Elbow – CFE (Cascade Fire Equipment) P/N: 10251-90 or similar
LOW PRESSURE TEST (3-5 PSI)

To perform the low pressure test fasten a length of suction hose to the engine or water tender (Figure 8). Use ratchet straps or another suitable method, as long as the suction hose is attached safely and securely to the ladder.

To adjust for size of the foot valve (e.g., 1½”, 3”, or other), use a combination of male-to-female adapters, increasers, and/or reducers to attach the foot valve to the suction hose (Figure 9). Fill the suction hose with 6 to 10 feet of water to obtain 3-5 psi (2’ of hose = 1 psi). The weight of the water provides the pressure on the foot valve. Check the foot valve for 3 to 5 minutes. There should be no leakage. If leakage occurs, replace the foot valve with one that does not leak.

Figure 8. Suction hose with foot valve attached to engine ladder.

Figure 9. Foot valve attached to suction line with various adapters as needed to adjust for foot valve size.

HIGH PRESSURE TEST (130 PSI)

To perform the high pressure test, first attach a wye or other suitable shut-off valve to the rear discharge (Figure 10). If a pressure gauge is not available on the equipment, attach a pressure gauge to the wye, then attach the 90 degree elbow and next attach the foot valve. The test set-up should resemble the one shown in Figure 10. Using the engine’s pump, increase the pressure to 130 psi. Check the foot valve for 3 to 5 minutes. There should be no leakage. If leakage occurs, replace the foot valve with one that does not leak.

Thanks to Carl Schaefer at U.S. Forest Service, San Dimas Technology and Development Center, for development of this test protocol.

Figure 10. Pressure valve attached to the foot valve.

RISK ASSESSMENT MATRIX

As we have learned, successful management of risk demands commitment and leadership from top management to the smart employees in the field. We must continue to work towards agreement on how we define and manage tolerable risk and discourage attitudes of apathy or fatalism. Clearly we cannot completely eliminate the risk. Moreover, sardonic remarks that the only way to avoid the danger is to stay out of the woods do not add value to the discussion. On the other hand, we must not engage full on with heads down and surrender our fate to so called luck, or simply dismiss the concern as an inherent, unavoidable part of a risky job. We have the experience and capability to safely manage hazards and are obligated to seize every opportunity to do better.

A problem when you have a number of possible risks is to decide which ones are worthy of further attention. The Risk Assessment Matrix is a simple graphical tool widely used in many professions worldwide to help prioritize risks.

There are two main dimensions to risk: (a) How likely it will occur (probability), and (b) The impact/effect (severity) that it would have, should it occur. One familiar model of quantifying risk is to assign a numeric value to these risks and to multiply these together. However, a problem with this quantitative approach is that high-probability/low-impact risks get the same score as high-impact/low-probability risks. The following Risk Assessment Matrix is a widely recognized and more effective method to assess risk.

The Risk Assessment Matrix simply puts Probability (likelihood) and Severity (effect/impact) on two sides of an x-y chart and then the risk are placed within this two-dimensional space (see chart below). This gives several advantages:

- High-probability/low-impact and high-impact/low-probability risks are differentiated.
- You can visually compare risk, thus asking the question ‘is this one more or less likely than that one?’ This plays to the human cognitive preference for paired comparison rather than absolute evaluation.
- Then the risks can be addressed from top right down to bottom left. High-probability/low-impact and high-impact/low-probability risk of equal risk exposure score will tend to be evaluated at around the same time.
- The process can be done on the wall with flipchart-paper, on a paper or computer format, or in many cases in your head.

### Unacceptable:
- Likely harm from an event must not be accepted. Must be reduced with administrative barriers of protection and/or engineering controls. Eliminate or avoid risk to maintain sufficient safeguards.

### Intolerable:
- Should be reduced with administrative and/or engineering controls. Risk should not be tolerated save in special/limited circumstances.

### Tolerable:
- Tolerable if further risk reduction (cost, time, effort) would be grossly disproportionate to improvement gained.

### Acceptable:
- Negligible given common safe job procedures are applied. Continual vigilance necessary to maintain assurance that risk remains at this level.

Appendix D: AQUATIC INVASIVE SPECIES of Concern to Firefighters and Disinfection Methods

The species fire operations are most likely to encounter, their distributions, all disinfection methods, and references.
**Zebra & Quagga Mussels**

*Dreissena polymorpha & Dreissena rostriformis bugensis*

**GENERAL INFORMATION:**

- **Quagga Mussel Distribution:** CA, NV, UT, AZ, CO, NM, OK, TX, midwest, Great Lakes region and NE US. For most up-to-date information on distribution, please see: [https://nas.er.usgs.gov/taxgroup/mollusks/zebramussel/](https://nas.er.usgs.gov/taxgroup/mollusks/zebramussel/)
- **Zebra Mussel Distribution:** CA, UT, CO, OK, KS, NE, SD, ND, LA, AR, MO, IA, MN, MS, TN, AL, KY, IN, other midwest and Great Lakes regions and NE US. For most up-to-date information on distribution, please see: [https://nas.er.usgs.gov/taxgroup/mollusks/zebramussel/](https://nas.er.usgs.gov/taxgroup/mollusks/zebramussel/)
- **Habitat:** Both mussels attach to hard surfaces in temperate lakes and slow rivers. Microscopic mussel larvae are released into open water where they swim about for several days before settling.
- **Fire Activities Posing Risk:** Most concern is with microscopic larvae present in water column. Larvae can survive for 5 days in internal tanks with residual water (summer months). Risks include: contact with untreated water; helicopter buckets, snorkels, and other drafting gear that capture bottom sediments, mud, or aquatic plants; internal tanks and hoses that retain residual untreated water.
- **Environmental Impacts:** Zebra and quagga mussels colonize water supply pipes and biofoul hydroelectric and nuclear power plants, public water plants, and industrial facilities. These species remove nutrients in aquatic ecosystems and litter beaches with sharp-edged shells.

**DISINFECTION PROTOCOLS:**

Asian Clam

Corbicula fluminea

General Information:

- **Distribution:** Almost all US states except MT, ND and ME. For most up-to-date information on distribution, please see: [https://nas.er.usgs.gov//queries/FactSheet.aspx?speciesID=92](https://nas.er.usgs.gov//queries/FactSheet.aspx?speciesID=92).
- **Habitat:** Lakes and streams, buried in sediments or larvae and juveniles drifting in currents.
- **Fire Activities Posing Risk:** Most concern is with larvae and juvenile clams in swept into water column. Risks include: contact with untreated water; helicopter buckets, snorkels, and other drafting gear that capture bottom sediments, mud, or aquatic plants; internal tanks and hoses that retain residual untreated water.
- **Environmental Impacts:** Asian clams can biofoul power plant and industrial water systems. Juveniles secrete a mucousy dragline and can be easily transported in currents. The clams also clog irrigation canals and drinking water pipes.

New Zealand Mudsnail

*Potamopyrgus antipodarum*

**General Information:**
- **Distribution:** WA, OR, CA, ID, MT, WY, UT, NV, AZ, CO, MN, IL, OH, PA, NY, and Canada. For most up-to-date information on distribution, please see: [https://nas.er.usgs.gov/taxgroup/mollusks/newzealandmudsnaildistribution.aspx](https://nas.er.usgs.gov/taxgroup/mollusks/newzealandmudsnaildistribution.aspx).
- **Habitat:** Streams and lakes, occurring on rocky substrates as well as aquatic plants.
- **Fire Activities posing risk:** Contact with untreated water; helicopter buckets, snorkels, and other drafting gear that capture bottom sediments, mud, or aquatic plants; internal tanks and hoses that retain residual untreated water.
- **Environmental impacts:** Mudsnails reproduce very quickly. It only takes a SINGLE snail can result in a colony of more than 40 million snails in just one year. New Zealand mudsnails can smother a streambed, crowding out the native aquatic species that provide food for fish.

Malaysian Trumpet Snail

_Melanoides tuberculata_

Also called: Red Rimmed Melania, Red Lipped Melania

General Information:
- **Distribution:** AZ, CA, CO, FL, HI, LA, MT, NC, NV, OR, UT, TX (possible in SD, VA and WY). For most up-to-date information on distribution, please see: [https://nas.er.usgs.gov/queries/FactSheet.aspx?SpeciesID=1037](https://nas.er.usgs.gov/queries/FactSheet.aspx?SpeciesID=1037).
- **Habitat:** Slow moving rivers and lakes, on mud and plants
- **Fire Activities Posing Risk:** Risks include: helicopter buckets, snorkels, and other drafting gear that capture bottom sediments, mud, or aquatic plants; internal tanks and hoses that retain residual untreated water
- **Environmental Impact:** This trumpet snail can outcompete native snails and alter ecosystem functions

Oriental Mystery Snail

*Cipangopaludina spp.*

Also called: Chinese Mystery Snail

**General Information:**

- **Distribution:** WA, OR, CA, ID, UT, AZ, CO, TX, NE, MO, GA, FL, NC, Great Lakes region, and northeastern US. For most up-to-date information on distribution, please see: [https://nas.er.usgs.gov/queries/FactSheet.aspx?SpeciesID=1044](https://nas.er.usgs.gov/queries/FactSheet.aspx?SpeciesID=1044).
- **Habitat:** Slow moving rivers and lakes, on mud and plants. Readily transported by equipment infested with snails hitchhiking on aquatic plants.
- **Fire Activities Posing Risk:** Helicopter buckets, snorkels, and other drafting gear that capture bottom sediments, mud, or aquatic plants; internal tanks and hoses that retain residual untreated water.
- **Environmental Impact:** These snails form dense populations and outcompete native species for food and habitat. They are intermediate hosts for parasitic worms and can transmit diseases that kill waterfowl. Some mystery snails prey on fish embryos. Snail shells often litter shorelines and clog screens of water intakes.

Spiny Waterflea

*Bythotrephes longimanus*

General Information:
- **Distribution:** Primarily in the Great Lakes Region of the US. For most up-to-date information on distribution, please see: [https://nas.er.usgs.gov/queries/FactSheet.aspx?SpeciesID=162](https://nas.er.usgs.gov/queries/FactSheet.aspx?SpeciesID=162).
- **Habitat:** Waterflea plankton (adults and juveniles) are free-swimming in water column of ponds and lakes; dormant (resting) eggs are in mud or silt.
- **Fire Activities posing risk:** Contact with untreated water; helicopter buckets, snorkels, and other drafting gear that capture bottom sediments, mud, or aquatic plants; internal tanks and hoses that retain residual untreated water.
- **Environmental Impact:** The rapidly reproducing spiny waterflea competes with small fish and fouls fishing gear. Larger fish that feed on waterfleas may die due to punctures from spines.

Didymo
*Didymosphenia geminata*

**General Information:**
- **Distribution:** WA, OR, CA, ID, MT, WY, CO SC, ND, AR, NC, VA WV PA, NY, NH, CT, AK, and Canada. For most up-to-date information on distribution, please see: [https://www.invasivespeciesinfo.gov/aquatics/didymo.shtml](https://www.invasivespeciesinfo.gov/aquatics/didymo.shtml).
- **Habitat:** Didymo is a single cell alga that attaches to submerged rocks in cold streams and rivers.
- **Fire Activities posing risk:** Contact with untreated water; helicopter buckets, snorkels, and other drafting gear that capture bottom sediments, mud, or aquatic plants; internal tanks and hoses that retain residual untreated water. Didymo can survive in residual tank water for <2 days in summer but up to 45 days in autumn (Kilroy et al. 2007).
- **Environmental Risk:** Didymo forms dense mats that trail downstream and can completely cover the substrate, smothering native plants, insects, and mollusks.

**Disinfection Protocols:**

Chytrid fungus

Batrachochytrium dendrobatidis

General Information:

- **Distribution**: Chytrid fungus occurs on most continents.
- **Habitat**: Zoospores are free-swimming in water column and can survive in wet mud or silt.
- **Fire Activities posing risk**: Contact with untreated water; helicopter buckets, snorkels, and other drafting gear that capture bottom sediments, mud, or aquatic plants; internal tanks and hoses that retain residual untreated water.
- **Environmental Effects**: This aquatic fungus feeds on living vertebrates and primarily affects the skin of amphibians. Because amphibians breathe and take up water through their skin, the disease causes widespread amphibian declines.

Whirling Disease

Myxobolus cerebralis

General Information:
- **Distribution:** WA, OR, CA, ID, NV, AZ, NM, UT, CO, NE, WY, ID, MT, MI, WI, OH, WV, VA, DE, MD, PA, NJ, CT, NY, MA, VT, NH, AK. For most up-to-date information on distribution, please see: [https://www.invasivespeciesinfo.gov/microbes/whirling.shtml](https://www.invasivespeciesinfo.gov/microbes/whirling.shtml).
- **Habitat:** Free-swimming microscopic larvae occur in water column, resistant spores in mud and bottom sediments. Spores can remain viable in mud for 12 years.
- **Fire Activities Posing Risk:** Risks include: contact with untreated water; helicopter buckets, snorkels, and other drafting gear that capture bottom sediments, mud, or aquatic plants; internal tanks and hoses that retain residual untreated water.
- **Environmental Effects:** Whirling disease afflicts trout species, causing spinal distortions and population declines.

General Information:
- **Distribution:** Great Lakes and St. Lawence River. For most up-to-date information on distribution, please see: [https://www.invasivespeciesinfo.gov/microbes/vhs.shtml](https://www.invasivespeciesinfo.gov/microbes/vhs.shtml).
- **Habitat:** Viral Hemorrhagic Septicemia (VHS) is carried in the water column and in aquatic invertebrates, such as snails and crustaceans, as well as fish parts.
- **Fire Activities Posing Risk:** Most concern is with virus free floating in the water column. Risks include: contact with untreated water; helicopter buckets, snorkels, and other drafting gear that capture bottom sediments, mud, or aquatic plants; internal tanks and hoses that retain residual untreated water.
- **Environmental Effects:** Over 50 fish species are susceptible to this disease which causes significant fish die-offs.

Spring Viremia of Carp

*Rhabdovirus carpio*

**General Information:**
- **Distribution:** NC, IL, WI OH, MN, MO, WA, Ontario. For most up-to-date information on distribution, please see: [https://www.glerl.noaa.gov/res/Programs/glansis/nas_database.html](https://www.glerl.noaa.gov/res/Programs/glansis/nas_database.html).
- **Habitat:** Spring Viremia of Carp (SVC) is carried in the water column and survives long periods in wet mud.
- **Fire Activities posing risk:** Most concern is with virus free floating in the water column. Risks include: contact with untreated water; helicopter buckets, snorkels, and other drafting gear that capture bottom sediments, mud, or aquatic plants; internal tanks and hoses that retain residual untreated water.
- **Environmental Effects:** This virus is a major cause of disease and death in carp and 50 other fish species.

Port Orford Cedar Root Disease (Phytophthora lateralis)
&
Sudden Oak Death (Phytophthora ramorum)

General Information:
- **Port Orford Cedar Root Disease Distribution**: WA, OR, CA. For most up-to-date information on distribution, please see: [http://www.issg.org/database/welcome/](http://www.issg.org/database/welcome/).
- **Sudden Oak Death Distribution**: CA, OR. For most up-to-date information on distribution, please see: [http://www.issg.org/database/welcome/](http://www.issg.org/database/welcome/).
- **Habitat**: Spores swim in standing water and can be carried large distances in flowing water; they also occur in soil.
- **Fire Activities Posing Risk**: Most concern is with spores carried in untreated water. Risks include: contact with untreated water; helicopter buckets, snorkels, and other drafting gear that capture bottom sediments, mud, or aquatic plants; internal tanks and hoses that retain residual untreated water.
- **Environmental Effects**: Port Orford cedars of all sizes may be killed by the root disease. Sudden oak death affects other trees as well as oaks, leading to widespread forest destruction.

1 Locate vehicle washing stations (with chlorinated water) where water will not run into streams. When refilling tenders/engines, fill with water first, pull 150’ away from the stream (or where overland flow will not run back into the stream), and then add the chlorine. Avoid dropping buckets of or directly releasing chlorine-treated water into streams or wetlands. Don’t treat water from streams that are uninfected with the root rot disease, unless it is for use at washing stations (to avoid unnecessary use of chlorine). (Southwest Oregon Interagency Fire Management Plan 2013)
Aquatic Invasive Plants

General Information:

- **Distribution:** Varies based on species. For most up-to-date information on distribution, please see: https://www.invasivespeciesinfo.gov/aquatics/main.shtml.

- **Habitat:** Aquatic plants are usually confined to shorelines and relatively shallow portions of waterbodies, though plant pieces can float throughout.

- **Fire Activities Posing Risk:** Contact with untreated water; helicopter buckets, snorkels, and other drafting gear that capture bottom sediments, mud, or aquatic plants; internal tanks and hoses that retain residual untreated water.

- **Environmental Effects:** Non-native aquatic plants clog waterways and threaten the diversity and survival of native species.
